Abnormal...

Cortical organization

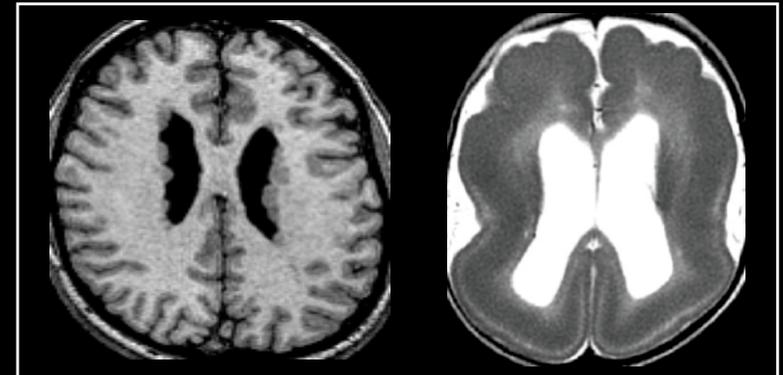

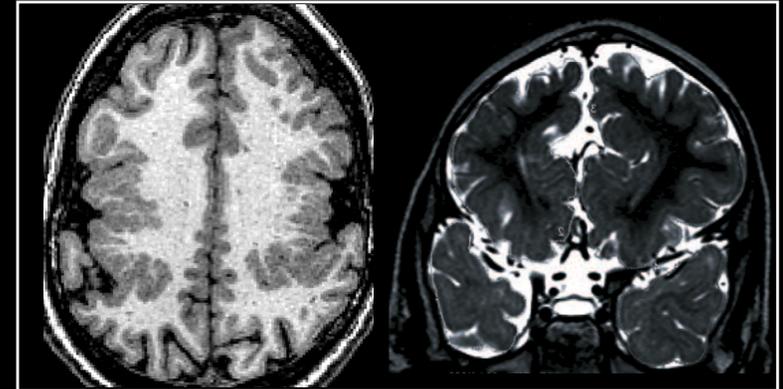

- Polymicrogyria
- Mild focal cortical dysplasia

Cell migration

- Heterotopia (PVNH, SCH)
- Lissencephaly

Cell proliferation

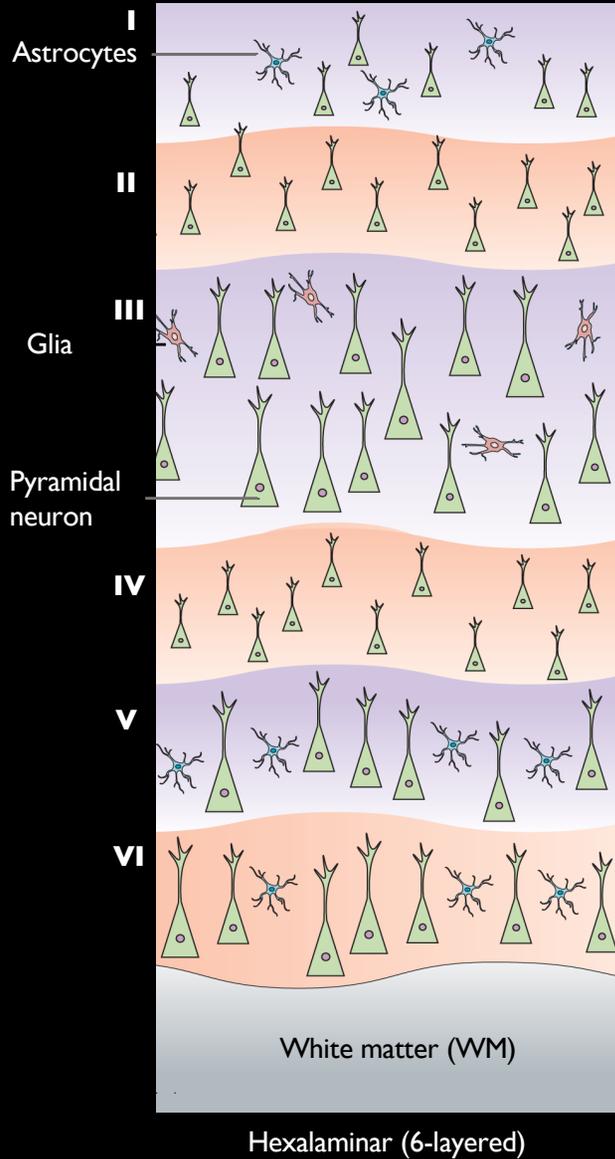

- Focal cortical dysplasia
- Micro-/Megalencephaly

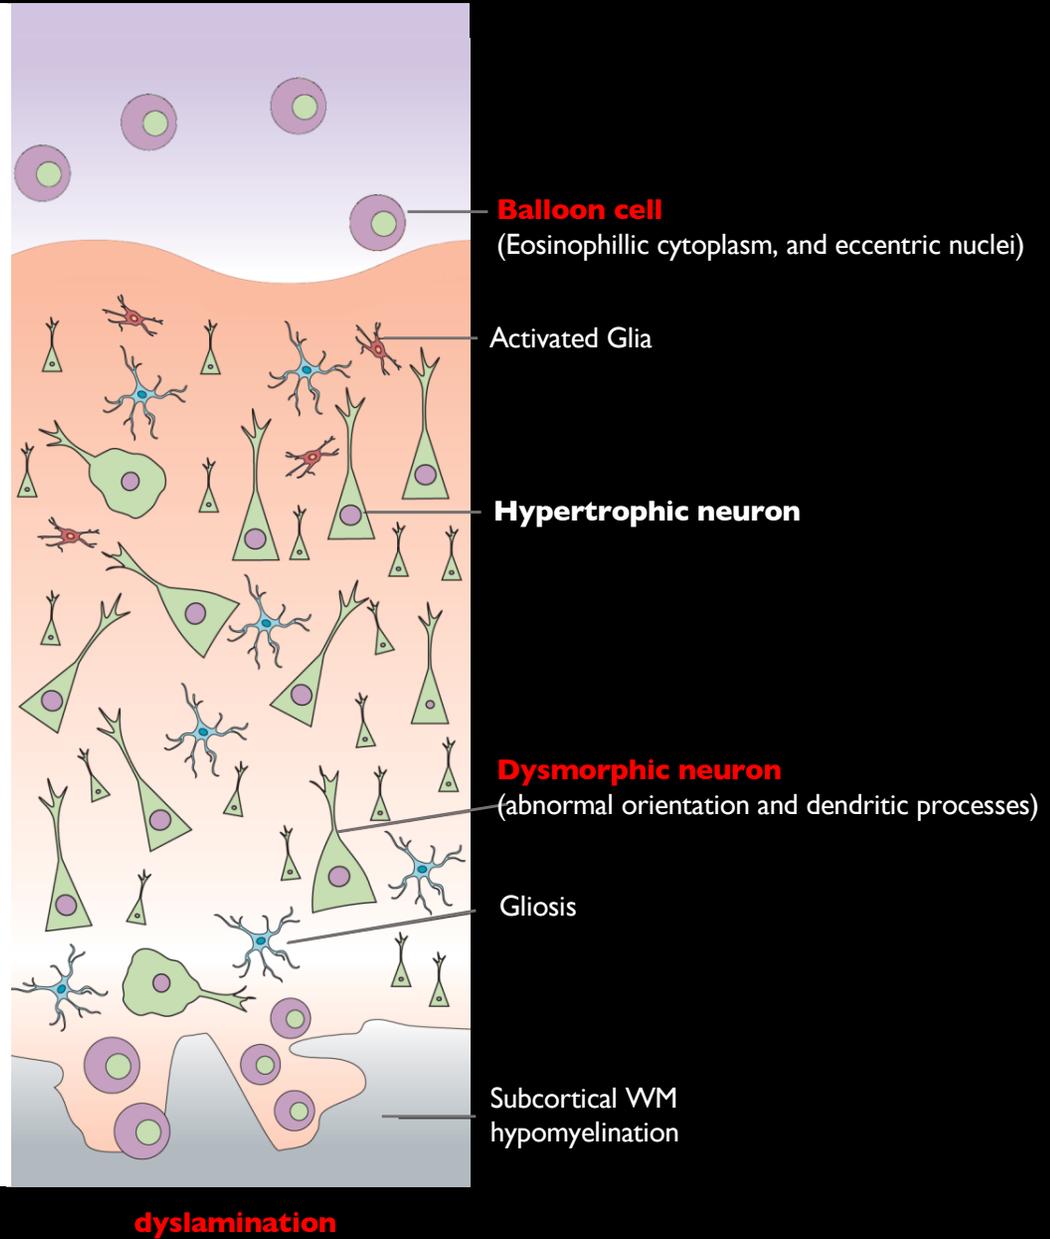

FOCAL CORTICAL DYSPLASIA

- Drug-resistant neocortical epilepsy
- Amenable to surgery if localized
- 40-60% good seizure control

Normal neocortex

Balloon cell

- Identifying subtype-specific imaging signatures may have potential clinical utility
 1. Optimize lesion detection (specific to certain histopathological types)
 2. Complement minimally invasive surgical procedures (e.g. thermal laser ablation)
 3. Guide and monitor pharmacological interventions (mTOR signaling inhibitor)

PURPOSE

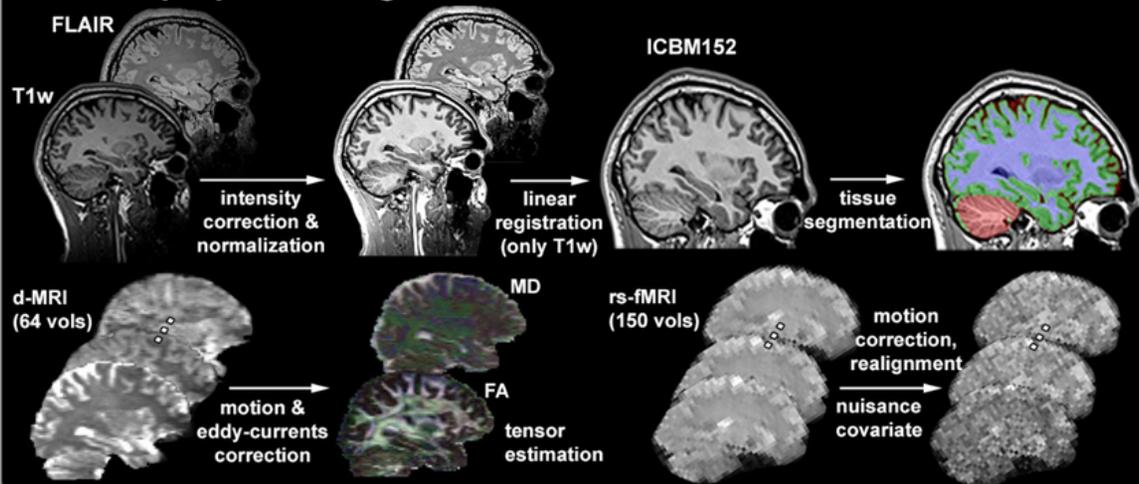

In-vivo lesion profiling and subtype prediction in focal cortical dysplasia type-II

Consecutive patients with drug-resistant epilepsy and histologically verified 9 FCD Type-IIA and 24 IIB

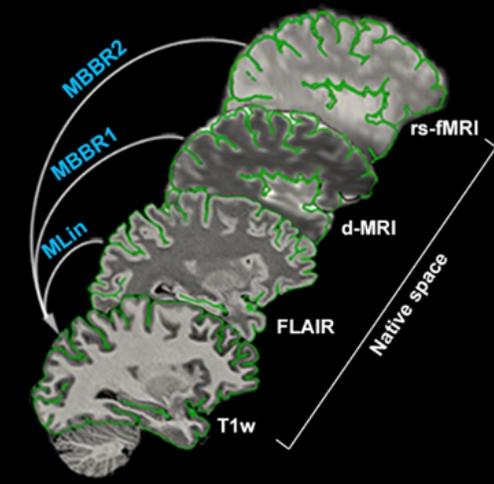

Multimodal MRIs (3T Siemens TimTrio, 32 channel head coil)

- 3D T1w MPRAGE ($1 \times 1 \times 1 \text{ mm}^3$)
- 3D FLAIR ($0.9 \times 0.9 \times 0.9 \text{ mm}^3$)
- 2D EPI-DTI ($2 \times 2 \times 2 \text{ mm}^3$, 64 directions)
- 2D rs-fMRI ($4 \times 4 \times 4 \text{ mm}^3$, 150 volumes)

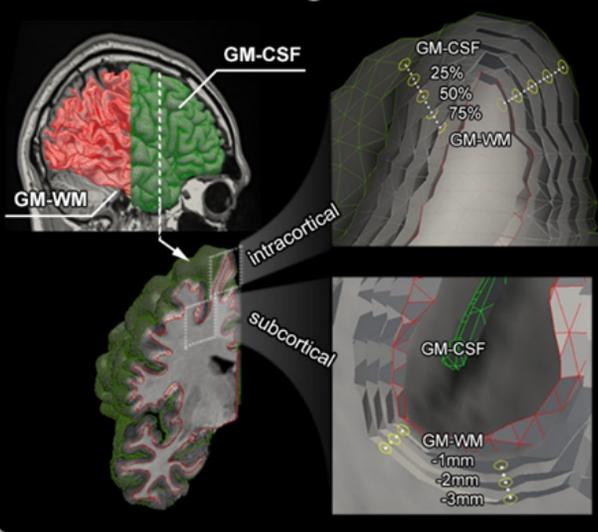

A - MRI preprocessing

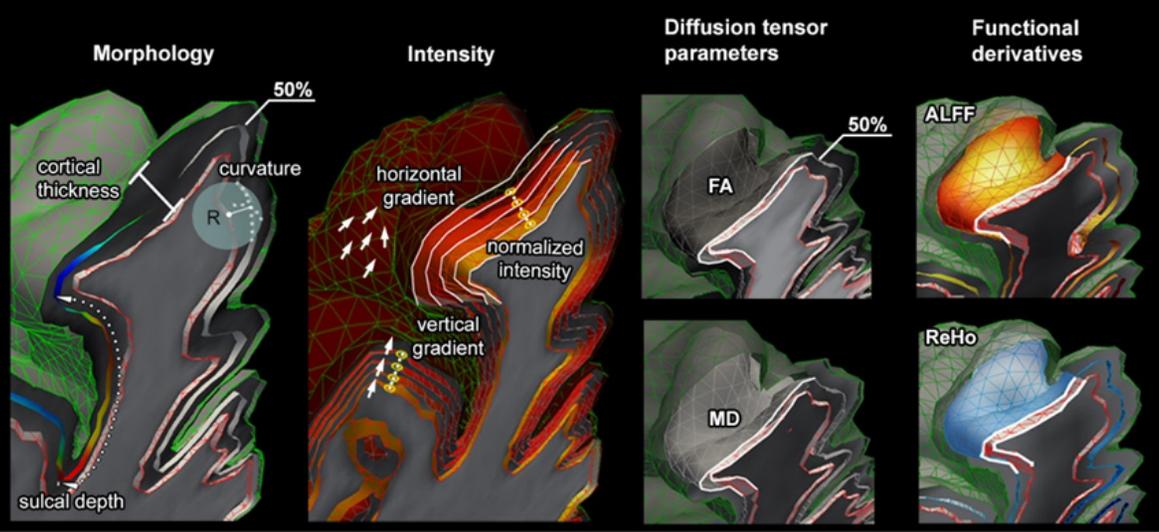

B - Multimodal data fusion

C - Multi-surface generation

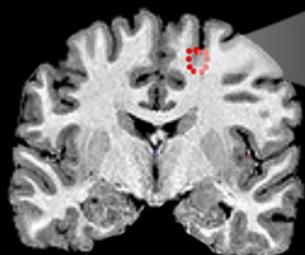

D - Feature extraction

E - Lesion profiling and subtype prediction

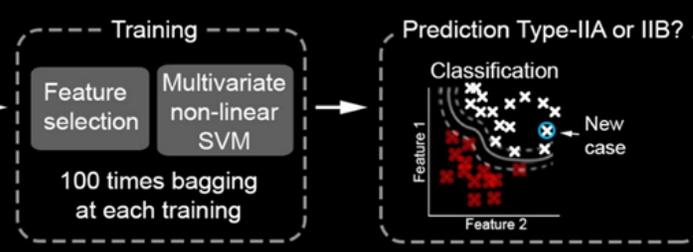

Manual lesion segmentation

Lesion profiling

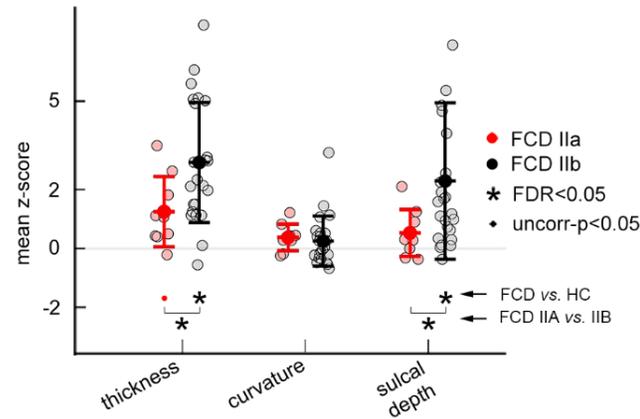

10-fold cross-validation (100 iterations)

Multi-surface lesion profiling

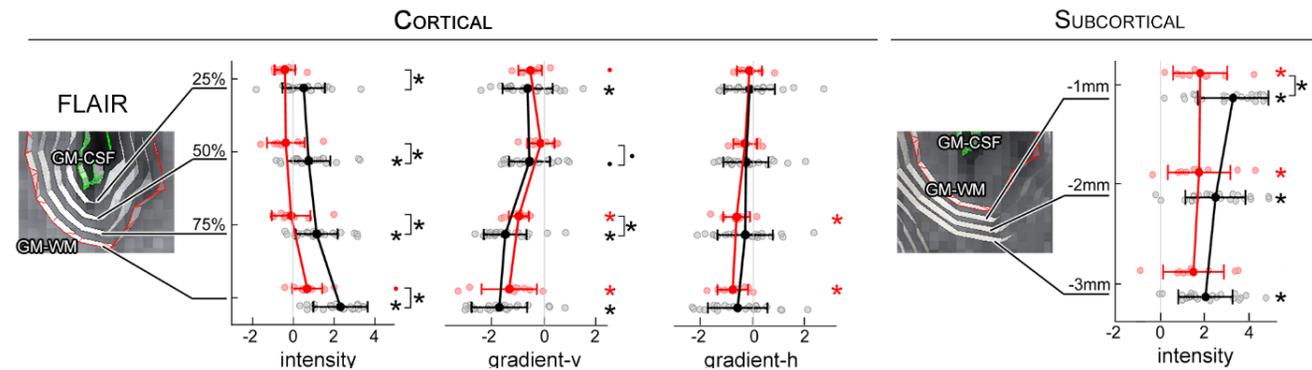

1. Morphology

2. Intensity

IIB: Abnormalities across all cortical and subcortical surfaces

IIA: Abnormalities clustered around the GM-WM interface

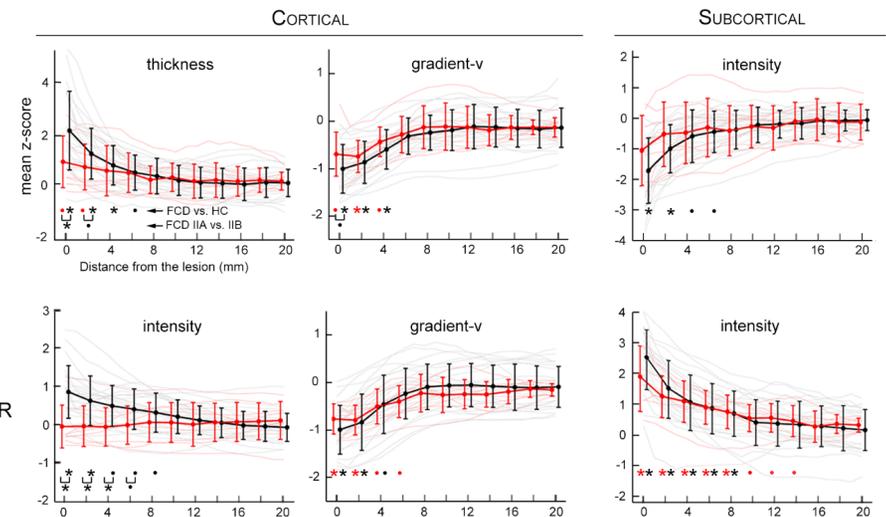

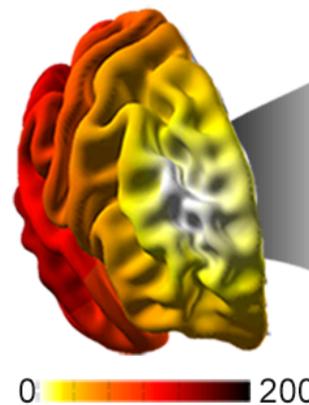

Distance-based lesion profiling

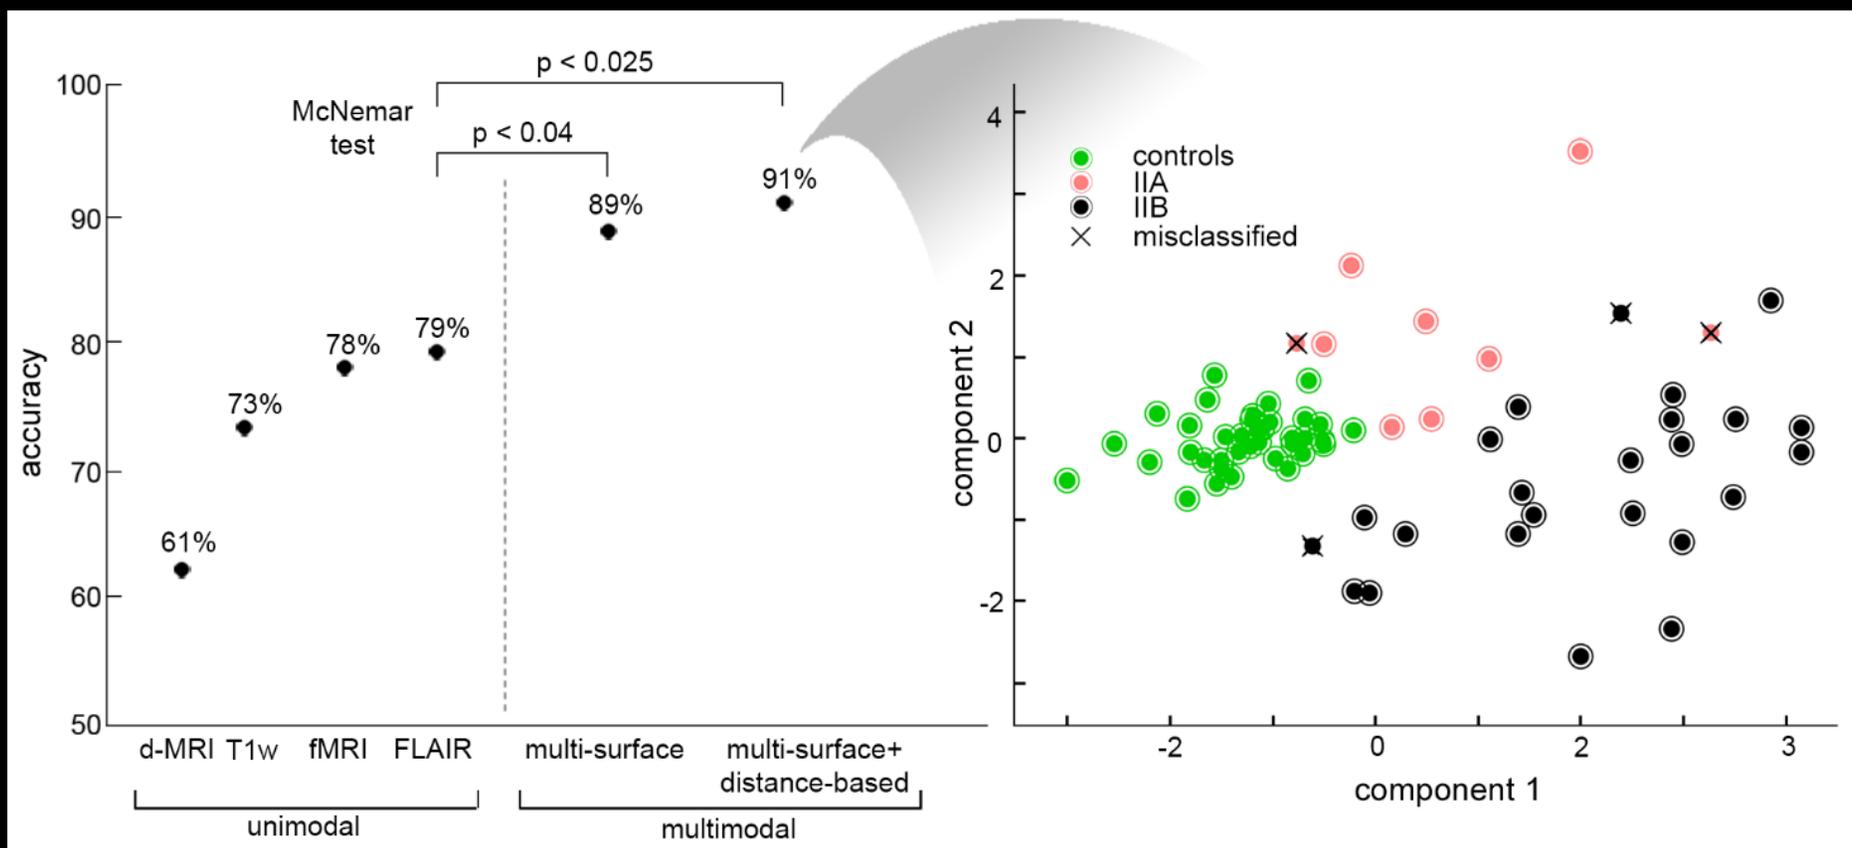

Pathological infiltration beyond the visible lesion in both subtypes

- Until 6-8 mm from the lesion
- Nevertheless, anomalies more marked in Type-IIb
- Except the reduced cortical FA specific to IIA

Geodesic distance

Histological subtype prediction

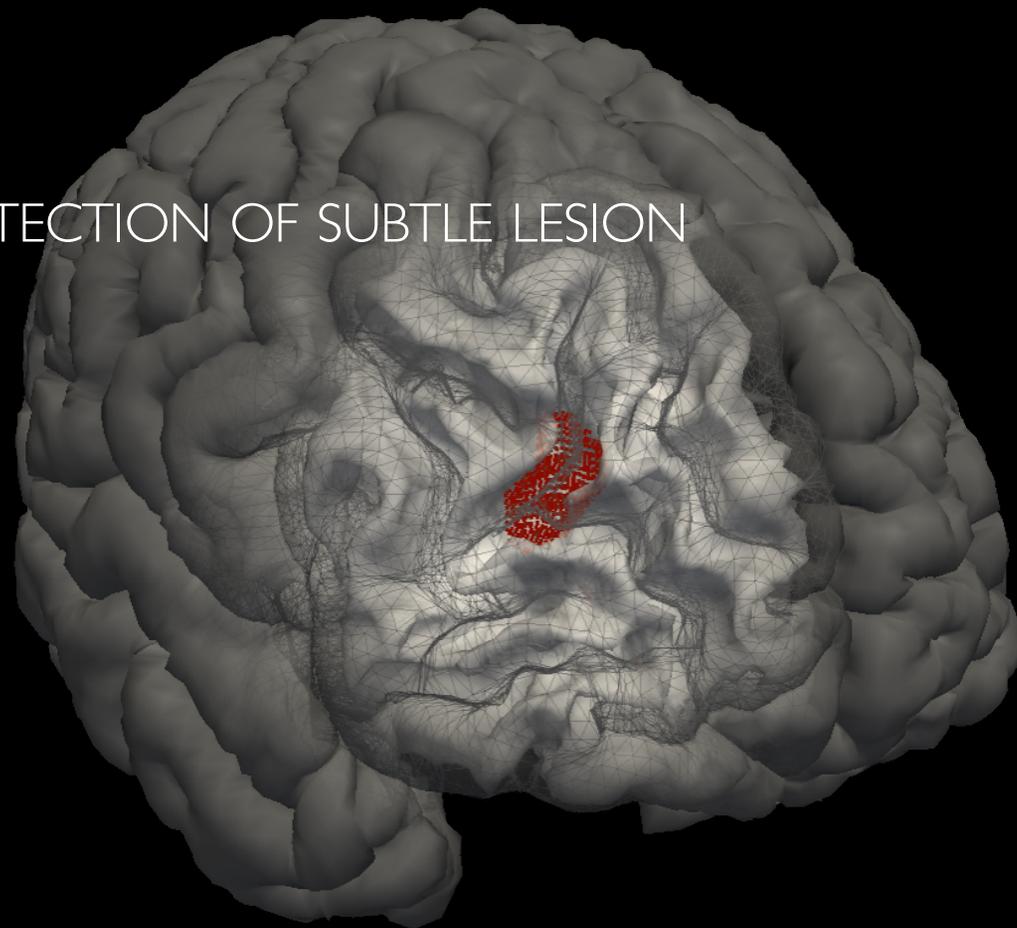

SI. CONCLUSION

- Multimodal, multiparametric MRI lesion profiling could dissociate FCD subtypes.
- Strikingly divergent subtype-specific patterns reflect different loads of underlying histopathology.
- In-vivo MRI prediction of histology could complement pre-surgical assessment (e.g., lesion detection) and possibly monitor emerging pharmacological interventions.

STUDY2

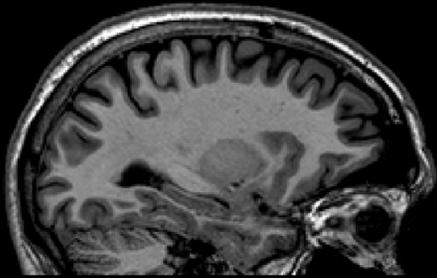

AUTOMATED DETECTION OF SUBTLE LESION

PURPOSE

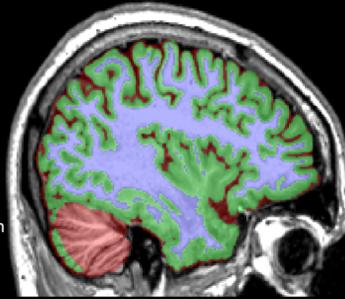

To detect automatically FCD type II in patients with extratemporal epilepsy initially diagnosed as MRI-negative on routine inspection, both at 1.5 and 3.0Tesla

Raw T1 MRI

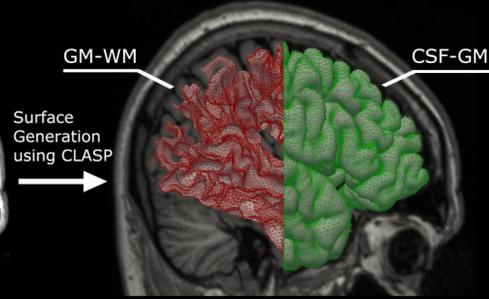

Intensity Correction
Spatial Normalization

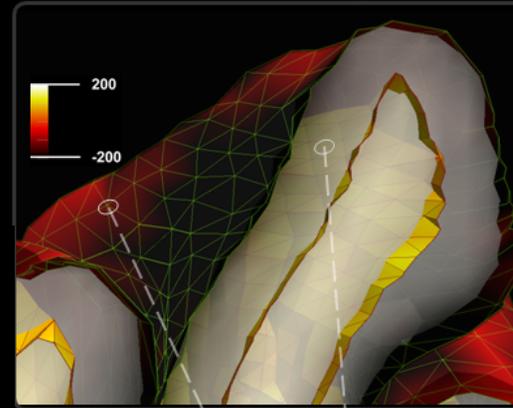

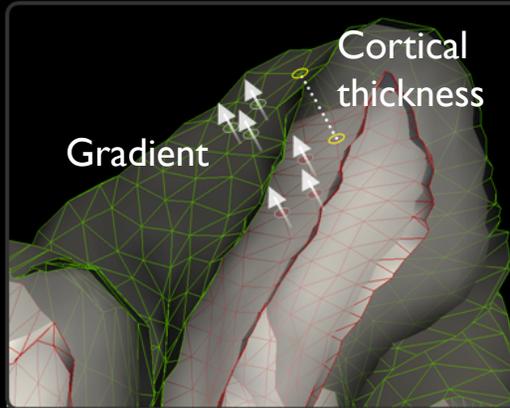

Segmentation Map

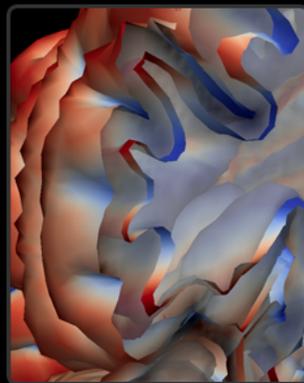

Cortical Surfaces

Relative intensity

$$\nabla I(x) = \frac{\partial I}{\partial x} i + \frac{\partial I}{\partial y} j + \frac{\partial I}{\partial z} k$$

2
-2

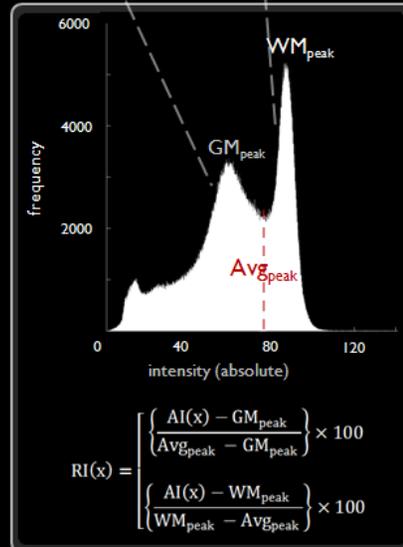

$$\Delta_{\text{surface}} D = 2\kappa_{\text{mean}}$$

Δ_{surface} : harmonic energy function

D: local depth

κ_{mean} : local mean curvature

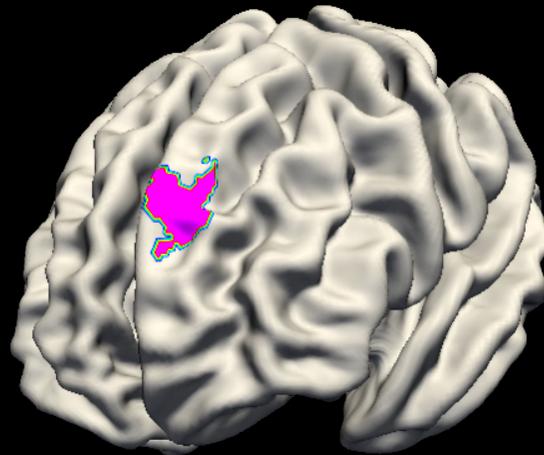

Sulcal depth & curvature

AUTOMATED LESION DETECTION USING MACHINE-LEARNING

1st CLASSIFICATION (vertex-wise)

Objective
recognize lesional vertices with highest
detection rate

Features
z-scores of GM thickness, GW-WM gradient,
intensity, sulcal depth, sulco-gyral curvature

Classifier
Linear discriminant

2nd CLASSIFICATION (cluster-wise)

Objective
reduce false positives while maintaining high
sensitivity

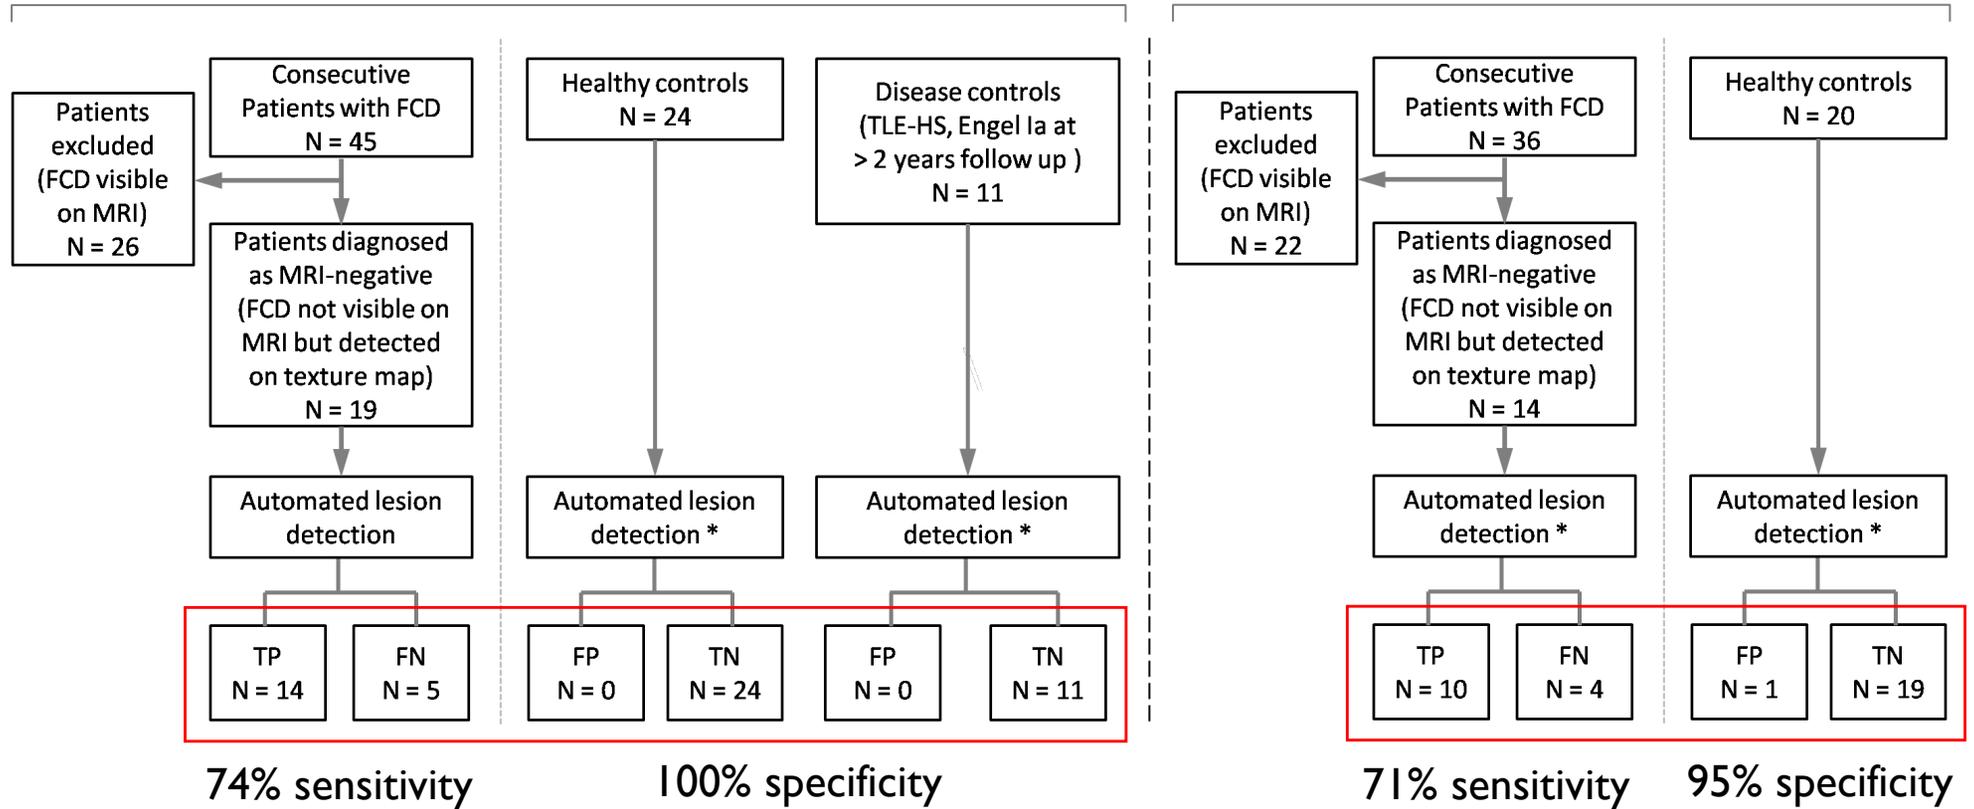

Features
mean, SD
skewness and kurtosis (texture)
spatial priors

Classifier
Linear discriminant

RESULTS

3.0 Tesla

1.5 Tesla

Nr. 16

S2. CONCLUSION

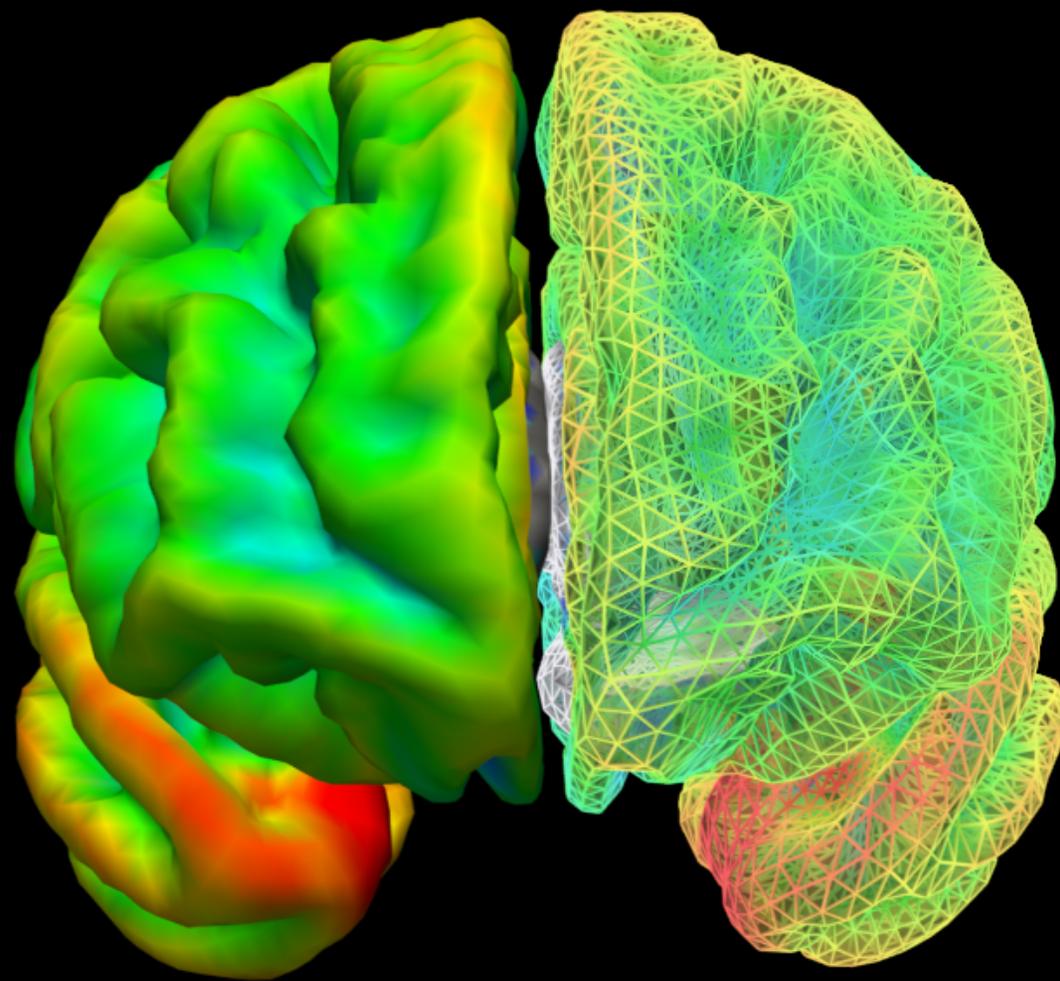

- Substantially increased sensitivity and specificity
- Generalizability across different cohorts, scanners and field strengths
- Machine learning may assist presurgical decision-making

Extralesional findings

- 50 % patients had 1-3 extra-lesional clusters
- Localized in frontal or central areas
- Same lobe as the primary lesion in 2 patients; contralateral hemisphere in 3; bilateral in 2
- Less abnormal features than primary FCD
- Most abnormal feature: sulcal depth
- No EEG correlates

- Almost all previous assessments have focused on primary lesion alone
- Integrity of whole-brain anomalies have not been systematically evaluated

STUDY3

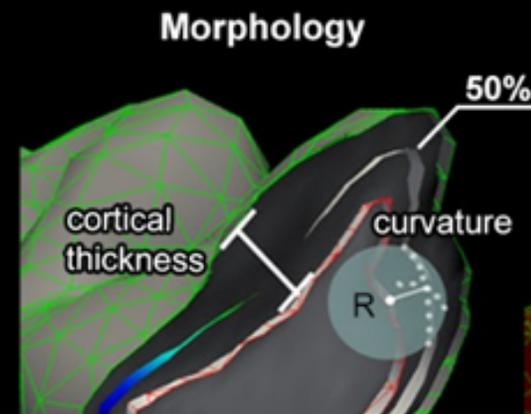

WHOLE-BRAIN MORPHOMETRY

PURPOSE

- 1) To assess whole-brain morphology in patients with dysplasia-related frontal lobe epilepsy
- 2) To compare the cohorts between FCD Type-I and II

- Two frontal lobe epilepsy cohorts with histologically-verified FCD (13 Type-I; 28 Type-II) & closely-matched 41 controls
- 1.5 T, 3D T1-FFE (isotropic voxel size of 1 mm³)

- Cortical thickness
- Gyral complexity (mean curvature)

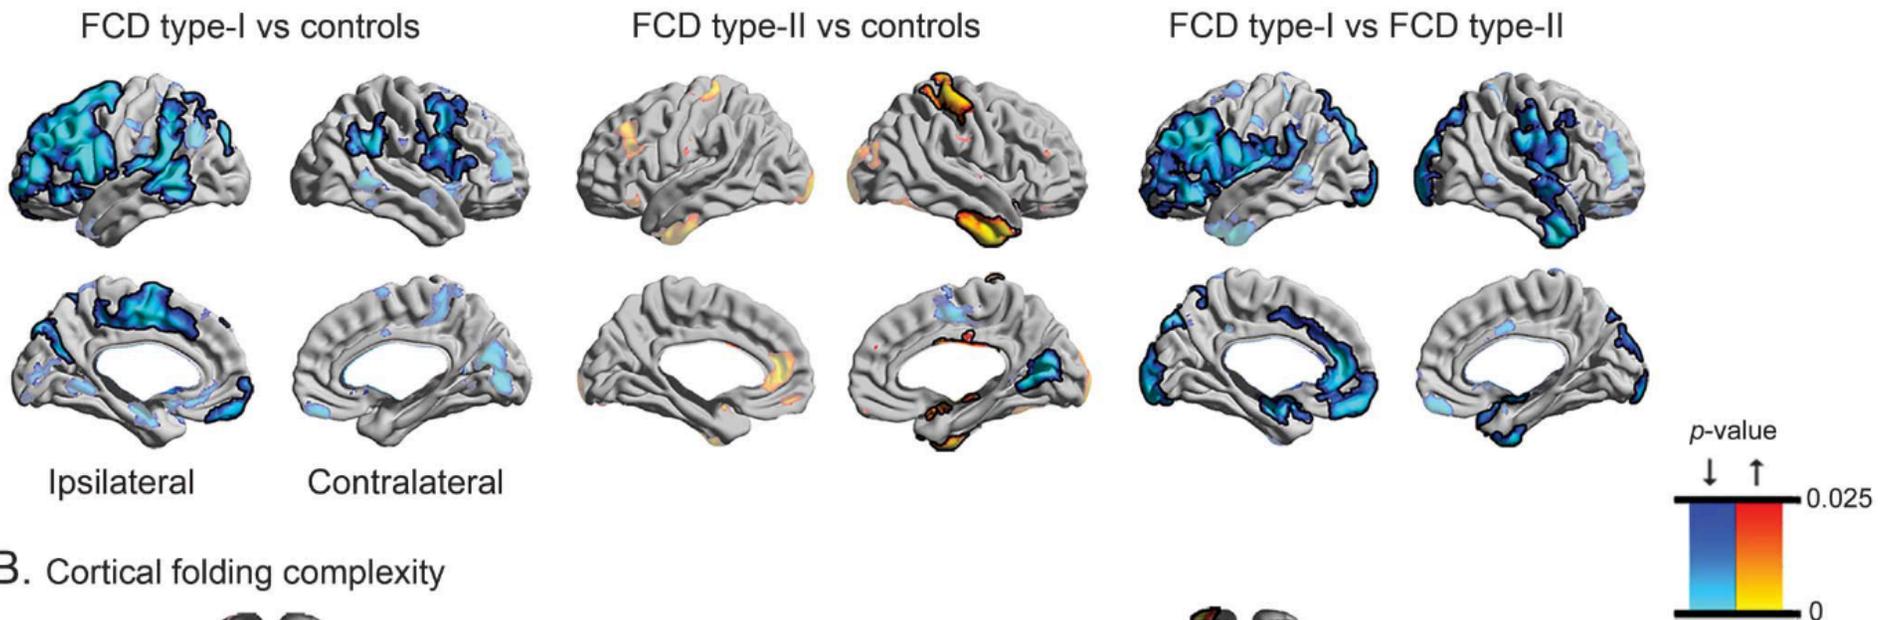

- Cross-sectional group comparison analysis (patients vs. controls; FCD Type-I vs. Type-II)

S3. Group-level comparisons

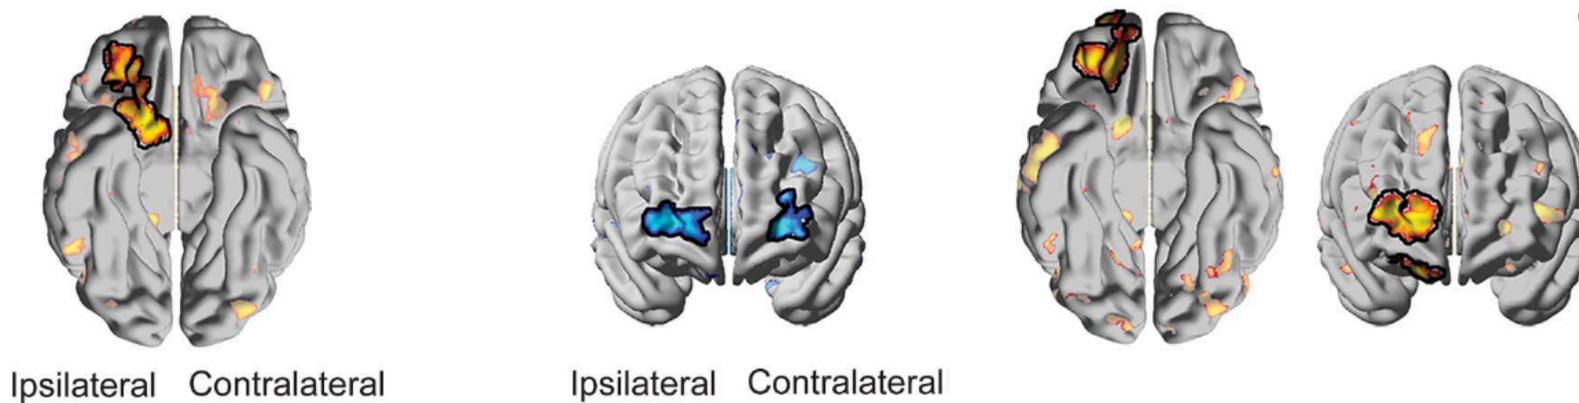

Hong SJ, et al *Neurology*, 2016

Figure 1 Group-level alterations in cortical thickness (A) and folding complexity (B) in patients with FCD

A. Cortical thickness

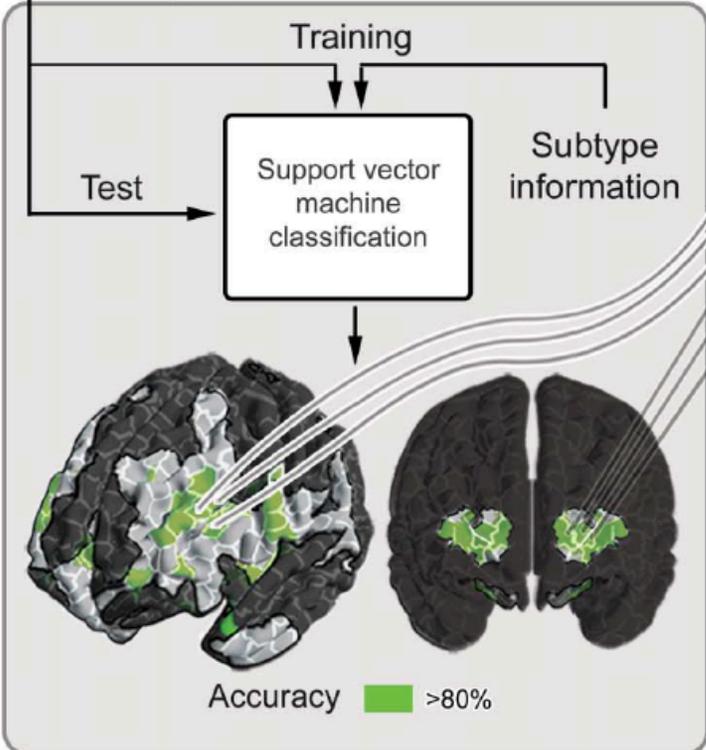

B. Cortical folding complexity

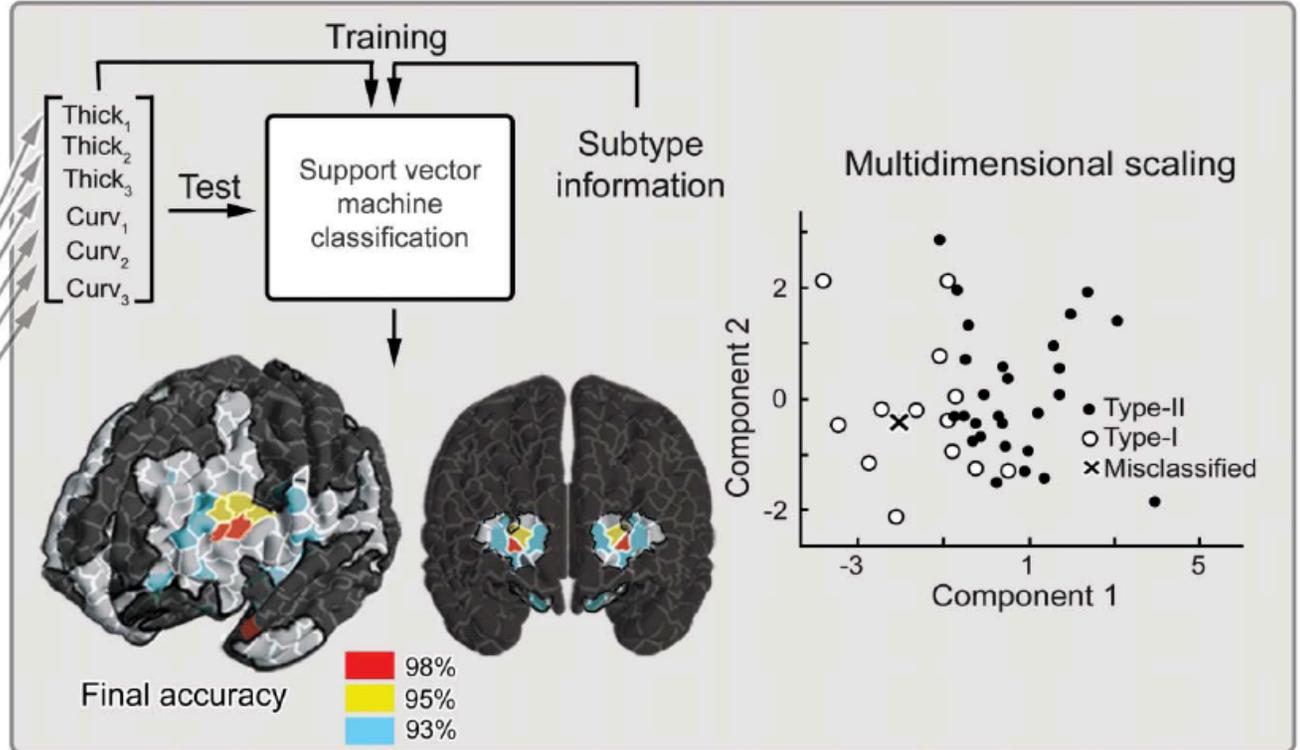

A. Feature generation

B. Single-parcel classification

C. Multiparcel classification

S3. CONCLUSION

- Extensive structural damage beyond the visible lesion
- Distinctive patterns between Type-I and Type-II.
- By successfully guiding multiple clinical tasks, our findings demonstrated high translational value for individualized diagnostics

SUMMARY

P1. In vivo profiling and subtype prediction of FCD Type-II:

- Reliable imaging markers to clearly dissociate histopathological subtypes

P2. Automated detection of FCD Type II in MRI-negative epilepsy

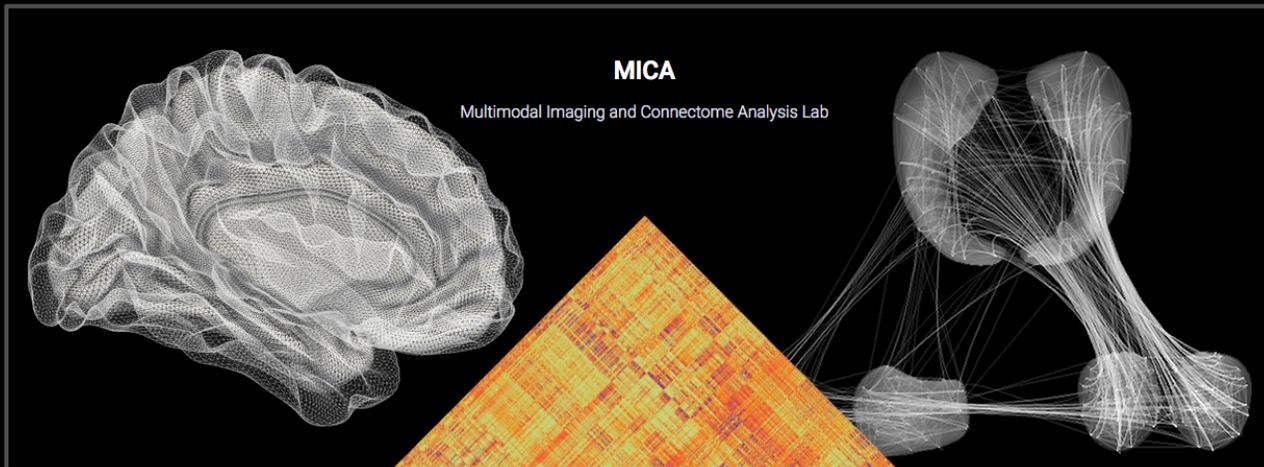

- Highly accurate detection performance across two different datasets

P3. Whole-brain MRI phenotyping in dysplasia-related frontal lobe epilepsy

- First demonstration that FCD is associated to whole-brain structural alterations.

SIGNIFICANCE

1. The power of multimodal MRI and image postprocessing
2. A new avenue to better understand fundamental pathological mechanisms in MCD, and clinically improve lesion detection and treatment strategies.
