

# The Flexibility Challenge

Energy Systems Integration for Low-Carbon Futures

François Bouffard, P.Eng., Ph.D.

Department of Electrical & Computer Engineering  
Trottier Institute for Sustainability in Engineering & Design (TISED)  
McGill University

Groupe d'études et de recherche en analyse des décisions  
(GERAD)

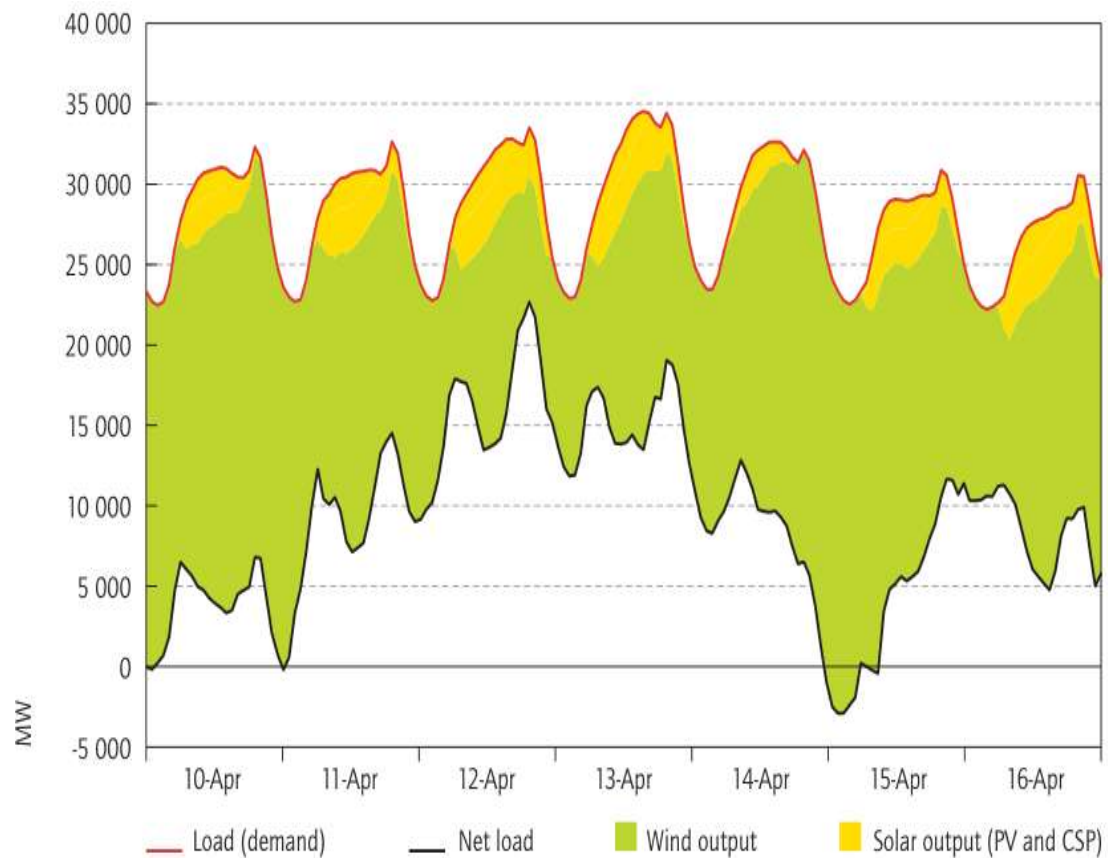

# Power & energy system decarbonization

- ▶ Electricity is the energy carrier *par excellence* for decarbonized energy systems
  - ▶ Increasing demand as fossil fuels are replaced by electricity
    - ▶ Transport, industrial processes, space heating, etc.
    - ▶ Increased dependency on having a resilient electric power supply infrastructure
  - ▶ Supply-side decarbonization via integration of low-carbon energy sources
    - ▶ Wind, solar, marine, biomass, hydro, etc., distributed geographically
    - ▶ Phasing out of traditional generation assets
- ▶ The Laws of physics are still here
  - ▶ Need for *energy system integration*

# Fundamental shifts in operation and planning - the challenges

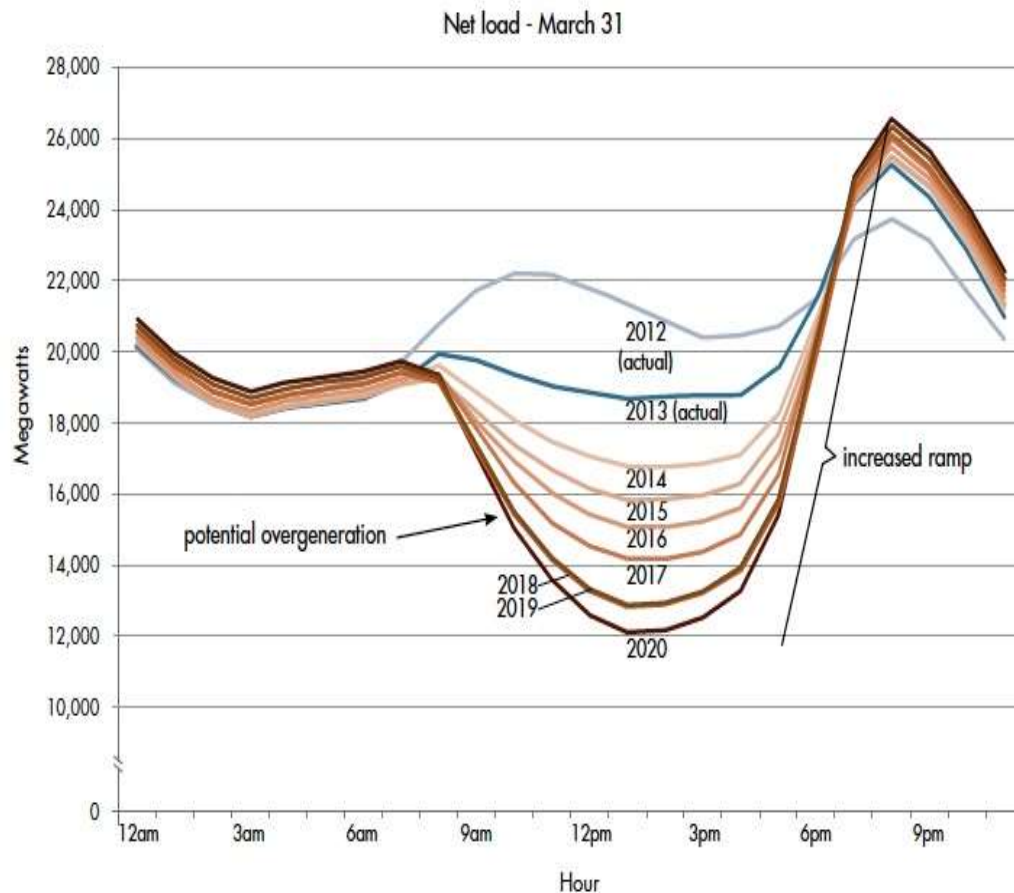

- ▶ Lower controllability
  - ▶ Phasing out of dispatchable generation assets, while integrating non- (or partially) dispatchable renewable generation
- ▶ Lower observability
  - ▶ Geographical dispersion of new generation all the way down to low-voltage distribution (e.g., behind-the-meter solar PV)
- ▶ Greater/different types of uncertainty
  - ▶ From outage-driven system planning to generation variability-driven planning
- ▶ Reliability paramount as electricity plays significant role in the economy

# Fundamental shifts in operation and planning - the challenges

- ▶ Handling these challenges require great *flexibility*
  - ▶ *The ability of a power system to alter its electricity production and consumption, in response to changing conditions, expected or otherwise*
  - ▶ Sources of flexibility
    - ▶ Generating assets - primary source
    - ▶ Consumers - space heating & cooling, sanitary water heating
    - ▶ Energy storage - batteries, thermal media
    - ▶ Networks - as conduits for flexibility
    - ▶ Institutions - markets, policies, system integration
  - ▶ How can we plan for flexibility?

# The flexibility challenge - three fundamental elements

- ▶ I. Flexibility requirement characterization
  - ▶ What? How much? Where? When?
- ▶ II. Flexibility resource characterization
  - ▶ Energy, power and ramping limitations, other inflexibilities
  - ▶ Cost of flexibility provision
- ▶ III. Matching flexibility requirements with available flexibility resources
  - ▶ Cost-benefit analysis trading off now against later decisions
  - ▶ How to do this in the long run & flexibility business models remain open questions

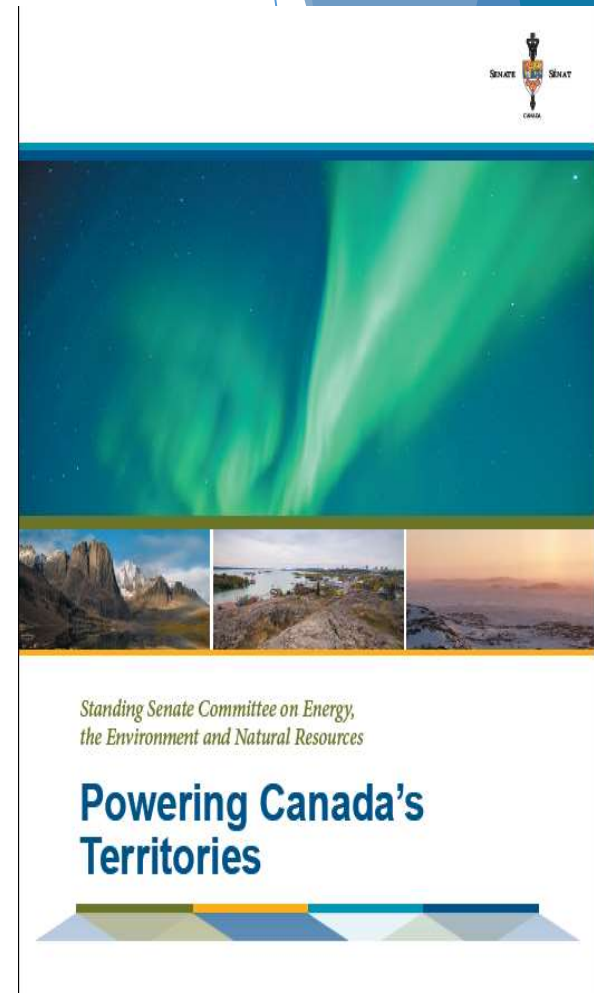

# Flexibility requirement characterization & integrated scheduling

Source: Nosair & Bouffard, 2016

# Canada's Northern communities: An opportunity to shine

- ▶ Displacing diesel through flexible operations
  - ▶ Techniques for more efficient use of generating assets through energy storage and consumer-side flexibility
  - ▶ Leveraging couplings with renewables
- ▶ System design techniques for remote microgrids
  - ▶ Finding best technological mix given economic, environmental and resiliency objectives and constraints

# Thank you
